In numerical analysis, the Bulirsch–Stoer algorithm is a method for the numerical solution of ordinary differential equations which combines three powerful ideas: Richardson extrapolation, the use of rational function extrapolation in Richardson-type applications, and the modified midpoint method, to obtain numerical solutions to ordinary differential equations (ODEs) with high accuracy and comparatively little computational effort.

$5 \times 10^{-(t+1)} |a| \leq 5 \times 10^{-t}$. With the abbreviation $\text{eps} := 5 \times 10^{-t}$, this can be written as (1.2. 2) $\text{rd}(x) = x(1 + \varepsilon)$, where $|\varepsilon| \leq \text{eps}$. The quantity $\text{eps} = 5 \times 10^{-t}$ is called the machine precision. In the binary system, $\text{rd}(x)$ is defined analogously: Starting with a decomposition $x =$.
